

The intervalx package^{*}

Valentin Dao[†]

Released 2025-11-16

Abstract

The purpose of this package is to extend interval's¹ functionalities by improving the main macro and adding a few new ones. Although the implementation has been modernised through the use of expl3, the approach is very similar to that used by Lars Madsen. As such, most keys will have the same name. Even though intervalx is presented as an extension of interval, new macros for composing inequalities have nevertheless been implemented.

1 Package options

Here are the options that can be declared using `\usepackage`:

| | | |
|--------------------------|-----------------------|-------------------------------|
| <code>soft fences</code> | <code>\boolean</code> | <code>(default: false)</code> |
|--------------------------|-----------------------|-------------------------------|

This key replaces open brackets with parentheses.

| | | |
|---------------------------|-----------------------|------------------------------|
| <code>smart fences</code> | <code>\boolean</code> | <code>(default: true)</code> |
|---------------------------|-----------------------|------------------------------|

This key automatically adapts the direction of the brackets to the presence of $+\infty$ and $-\infty$

| | | |
|------------------------|---------------------|---------------------------|
| <code>separator</code> | <code>\token</code> | <code>(default: ,)</code> |
|------------------------|---------------------|---------------------------|

Controls the character inserted between the interval endpoints.

2 Typeset an interval

`\interval` * $\langle keys \rangle$ $\{ \langle list\ of\ endpoints \rangle \}$

To typeset an interval, simply use the macro in math mode, entering the endpoints in the form of a list:

| \LaTeX code | Result |
|----------------------------------------------------------------------|--------------|
| <pre> 1 \begin{equation} 2 \interval{a, b} 3 \end{equation} </pre> | $[a, b]$ (1) |

open To change the direction of the brackets, use the option provided here.
open right
open left

| \LaTeX code | Result |
|---------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| <pre> 1 \begin{gather} 2 \interval[open right]{a, b} \\ 3 \interval[open left]{a, b} \\ 4 \interval[open]{a, b} 5 \end{gather} </pre> | $[a, b[$ (2) $]a, b]$ (3) $]a, b[$ (4) |

The direction of the brackets also adapts itself to $-\infty$ and $+\infty$, provided that the corresponding option remains enabled.

| \LaTeX code | Result |
|----------------------------------------------------------------------------------|---------------------------|
| <pre> 1 \begin{equation} 2 \interval{-\infty, +\infty} 3 \end{equation} </pre> | $] -\infty, +\infty[$ (5) |

scaled big, Big, bigg, Bigg

It is also possible to adjust the brackets/parentheses' size through the scaled key, which has the same usage as in the interval package.

| \LaTeX code | Result |
|---------------|--------|
|---------------|--------|

| | | | |
|---|---------------------------------------------------------------|-----------------------------------------|-----|
| 1 | <code>\begin{equation}</code> | | |
| 2 | <code>\interval[scaled=bigg]{\frac{1}{2}, \frac{3}{2}}</code> | $\left[\frac{1}{2}, \frac{3}{2}\right]$ | (6) |
| 3 | <code>\end{equation}</code> | | |

The starred variant typesets integer intervals by using the `stmaryrd` package.² All the keys described above are compatible with these symbols.

| \LaTeX code | Result |
|----------------------------------|-------------------------------|
| 1 <code>\begin{equation}</code> | |
| 2 <code>\interval*[2, 10]</code> | $\llbracket 2, 10 \rrbracket$ |
| 3 <code>\end{equation}</code> | (7) |

```

\ointerval *{<open, keys>}{<endpoints>}
\linterval *{<open left, keys>}{<endpoints>}
\rinterval *{<open right, keys>}{<endpoints>}

```

Finally, the package provides short hands through these three macros:

| \LaTeX code | Result |
|----------------------------------------------------------------------------|-----------------------------------------|
| 1 <code>\begin{gather}</code> | |
| 2 <code>\ointerval[scaled=bigg]{\frac{1}{2}, \frac{9}{2}}\backslash</code> | $\left]\frac{1}{2}, \frac{9}{2}\right[$ |
| 3 <code>\linterval{3, 8}\backslash</code> | $]3, 8]$ |
| 4 <code>\rinterval{3, 8}</code> | $[3, 8[$ |
| 5 <code>\end{gather}</code> | (8) (9) (10) |

3 Interval product, union, and intersection

`intervalx` also makes it easier to typeset product, union, and intersection relations between intervals.

²See on CTAN

3.1 Product

`\xinterval` [*<keys>*]{*<*-list>*}

For the product, the main argument takes the same form as with `\interval`, but the different intervals are delimited by an asterisk.

Mnemonic: The “x” at the beginning of the macro name evokes the product symbol \times , while the asterisk is a way of denoting it in programming.

| L ^A T _E Xcode | Result |
|-----------------------------------------------------------------------------------------------|-----------------------------------------------------|
| <pre> 1 \begin{equation} 2 \xinterval{2, 10 * 1, 15 * -3, 3 19} \end{equation}</pre> | $[2, 10] \times [1, 15] \times [-3, 19] \quad (11)$ |

To combine this macro with the keys of `\interval`, the latter must be specified as a list delimited by semicolons (the comma being already used to separate the different keys). Here is an example to clarify this point.

| L ^A T _E Xcode | Result |
|-----------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|
| <pre> 1 \begin{equation} 2 \xinterval[open right, scaled= 3 Big; open left, scaled=Big]{2, 10 * 1, 15} \end{equation}</pre> | $\left[2, 10 \left[\times \right] 1, 15 \right] \quad (12)$ |

3.2 Union

`\uinterval` [*<keys>*]{*</-list>*}

Similarly, interval union is typeset using the vertical bar as a delimiter.

Mnemonic: The “u” at the beginning of the macro name evokes the union symbol \cup , while the vertical bar is a way in programming to denote the logical *or*.

| L ^A T _E Xcode | Result |
|-------------------------------------|--------|
|-------------------------------------|--------|

| | | | |
|---|----------------------------------------|------------------------|------|
| 1 | <code>\begin{equation}</code> | | |
| 2 | <code>\uinterval{2, 10 1, 15}</code> | $[2, 10] \cup [1, 15]$ | (13) |
| 3 | <code>\end{equation}</code> | | |

3.3 Intersection

`\ninterval` [*keys*] {&-*list*}

Again, interval intersection is typeset using the ampersand as a delimiter. The use of keys is also identical to `\xinterval` and `\uinterval`.

Mnemonic: The “n” evokes the intersection symbol \cap , with the ampersand denoting the logical *and* in programming.

| L ^A T _E Xcode | Result |
|-------------------------------------------------|---------------------------|
| 1 <code>\begin{equation}</code> | |
| 2 <code>\ninterval{3, 20 & \pi, e^3}</code> | $[3, 20] \cap [\pi, e^3]$ |
| 3 <code>\end{equation}</code> | (14) |

4 Inequalities

`\ineq` * [*keys*] {*list of bounds*} [*variable*]

The composition of inequalities is quite similar to that of intervals, with a few differences. The keys `open right`, `open left` and `open` are also available to make it easy to write strict or non-strict inequalities. In addition to the bounds, you can also specify the variable, which defaults to x . Finally, the starred variant of the macro uses the alternative symbols from `amssymb` for non-strict inequalities.

| L ^A T _E Xcode | Result |
|-------------------------------------|--------|
|-------------------------------------|--------|

| | | | |
|---|---------------------------------------|-------------------|------|
| 1 | <code>\begin{gather}</code> | $a \leq x \leq b$ | (15) |
| 2 | <code>\ineq{a, b}\</code> | $a \leq y \leq b$ | (16) |
| 3 | <code>\ineq*[a, b]{y}\</code> | $a \leq x < b$ | (17) |
| 4 | <code>\ineq[open right]{a, b}\</code> | $a < x \leq b$ | (18) |
| 5 | <code>\ineq[open left]{a, b}\</code> | $a < x < b$ | (19) |
| 6 | <code>\ineq[open]{a, b}</code> | | |
| 7 | <code>\end{gather}</code> | | |
